CompleNet 2015

Summary

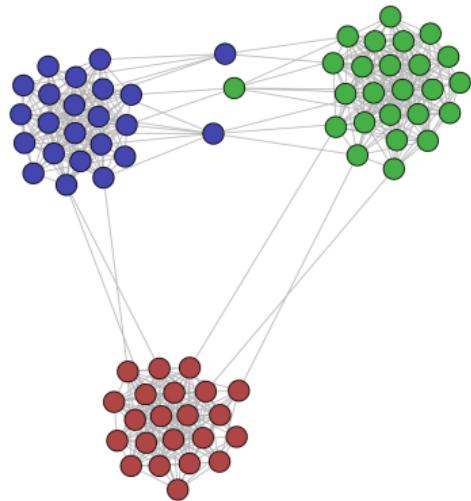

- ① Link community
- ② Expected Nodes : a new quality function
- ③ Tests with LF benchmark
- ④ Conclusion and perspectives

Community Detection

Node community

Link community

Node community

Input :
A graph, $G = (V, E)$.

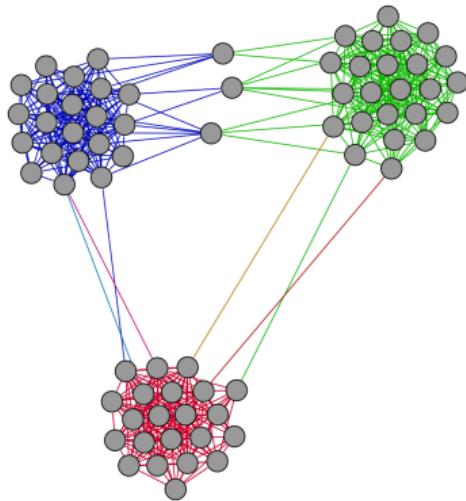

Output :
A partition \mathcal{P} of V .

S. Fortunato.

Community detection in graphs.

Example in a email dataset.
Communities : groups of people.

Link community

Example in a email dataset.
Communities : threads.

Input :
A graph, $G = (V, E)$.

Output :
A partition \mathcal{P} of E .

Expected Nodes : a new quality function

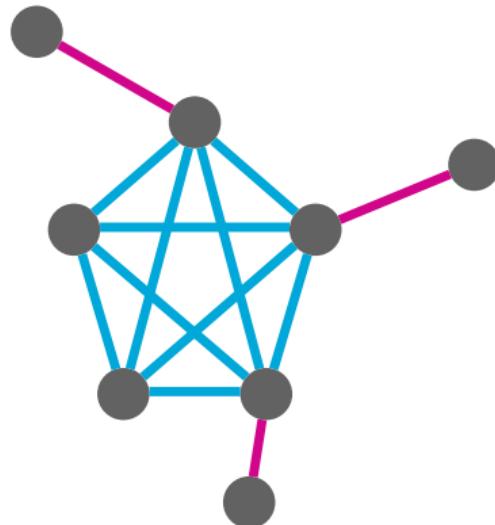

Outline of the quality function

Why is the group of blue links relevant ?

Outline of the quality function

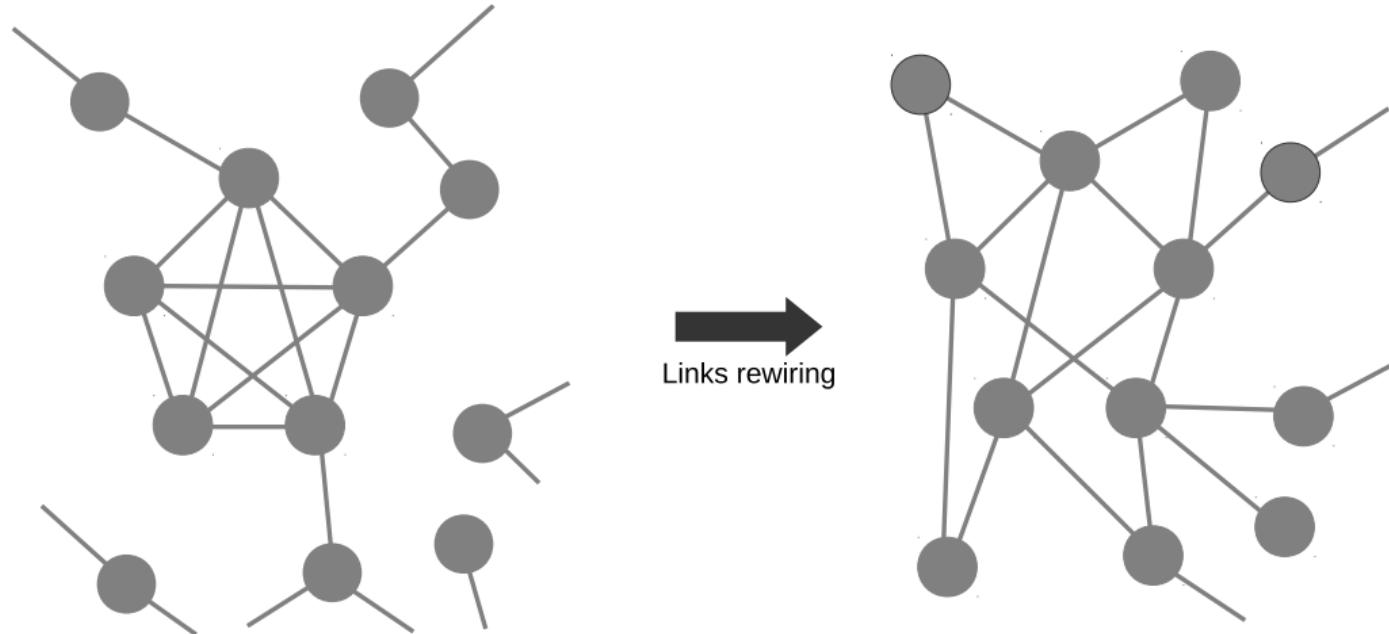

Why is the group of **blue** links relevant ?

Dense **blue links** and sparse **pink links** compare to what could be expected in the **configuration model**.

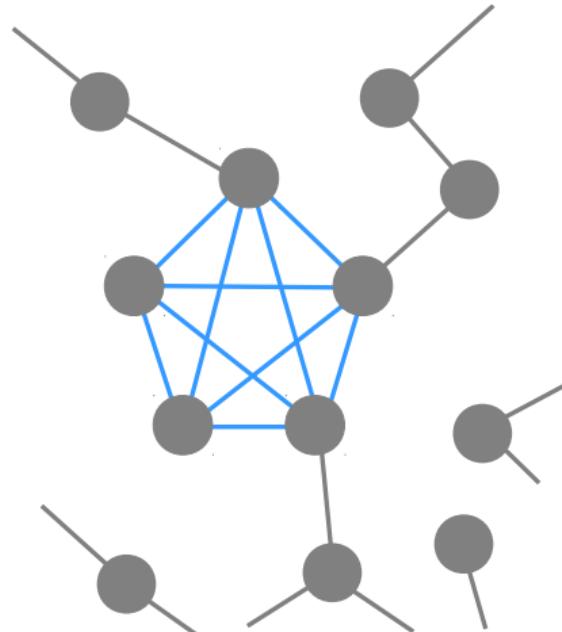

The idea behind Expected Nodes

Compare observed nodes to expected one :

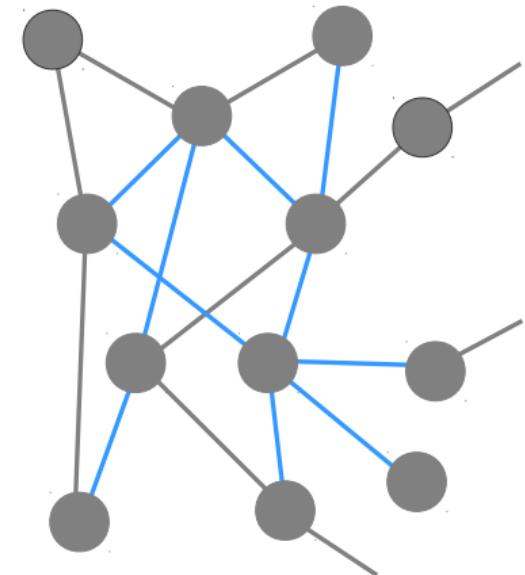

The idea behind Expected Nodes

Compare observed nodes to expected one :

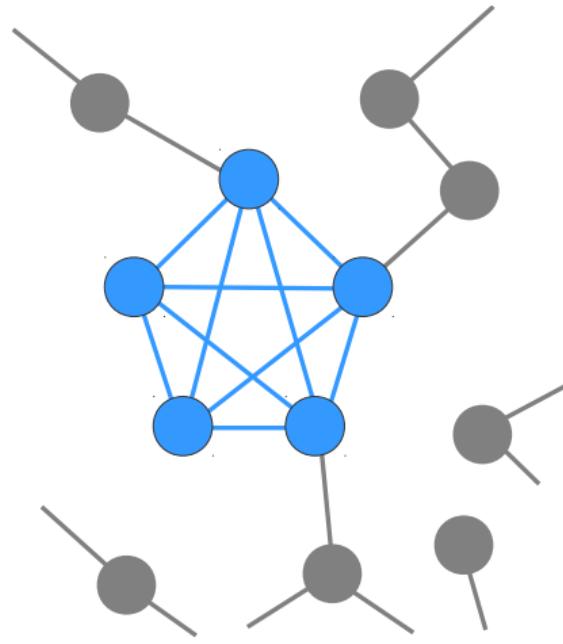

Links rewiring

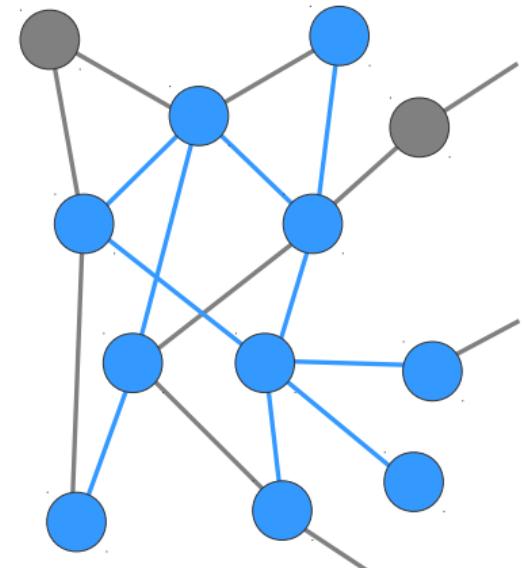

The idea behind Expected Nodes

Compare observed nodes to expected one :

Links rewiring

Internal quality function

L : set of **links**, $V(L)$: internal nodes of L .

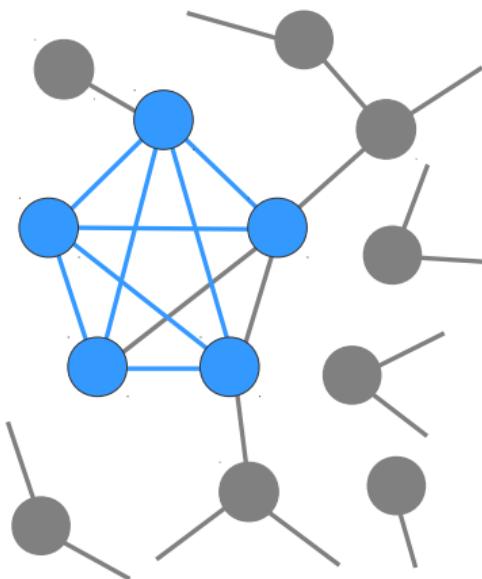

The internal quality of group L is :

$$Q_{in}(L) = \frac{\mathbb{E}[V(L)] - |V(L)|}{\mathbb{E}[V(L)]}$$

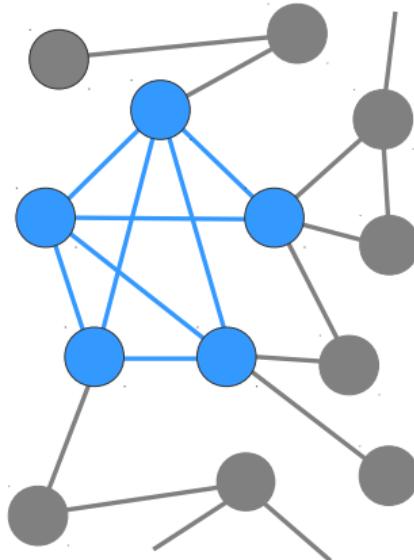

$\mathbb{E}[V(L)]$: sum of random variable with hypergeometric distribution.

External quality function

Compare adjacent nodes to expected ones :

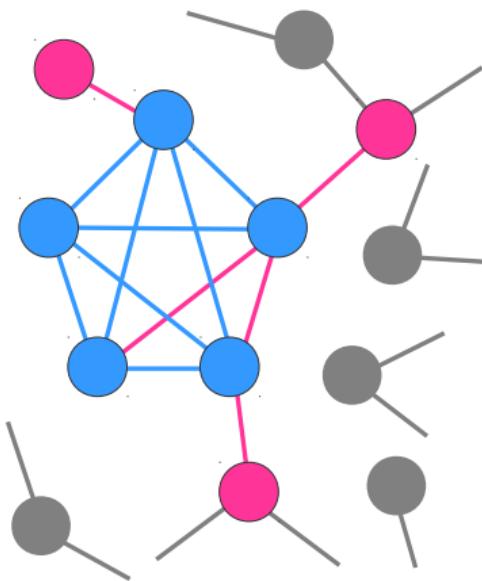

Rewire **non internal** links

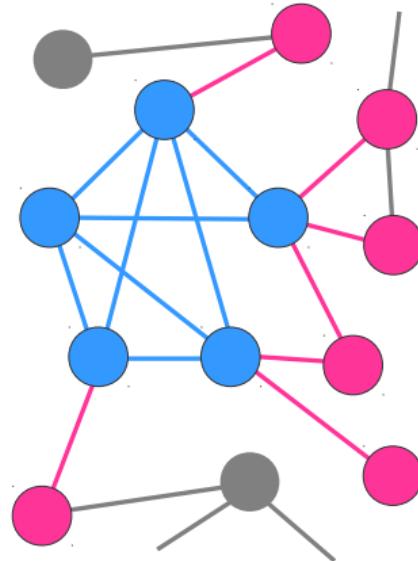

External quality function

Compare adjacent nodes to expected ones :

$$\text{card}(\textcolor{pink}{\bullet}) = 3$$

Rewire **non internal** links

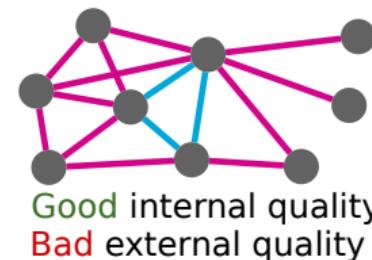

$$\text{card}(\textcolor{pink}{\bullet}) = 6$$

Combining both quality functions

$|L_{out}|$: set of adjacent links to L.

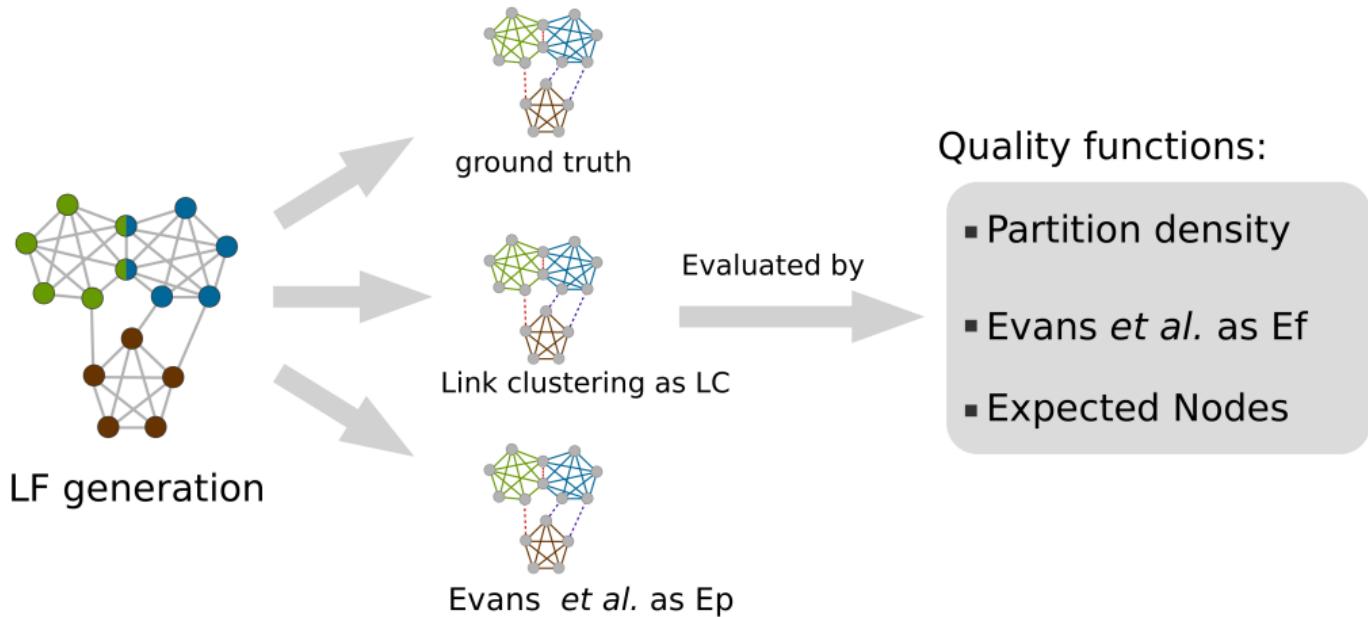

$Q_{ext}(L_{out})$ computed in a similar way as $Q_{in}(L)$.

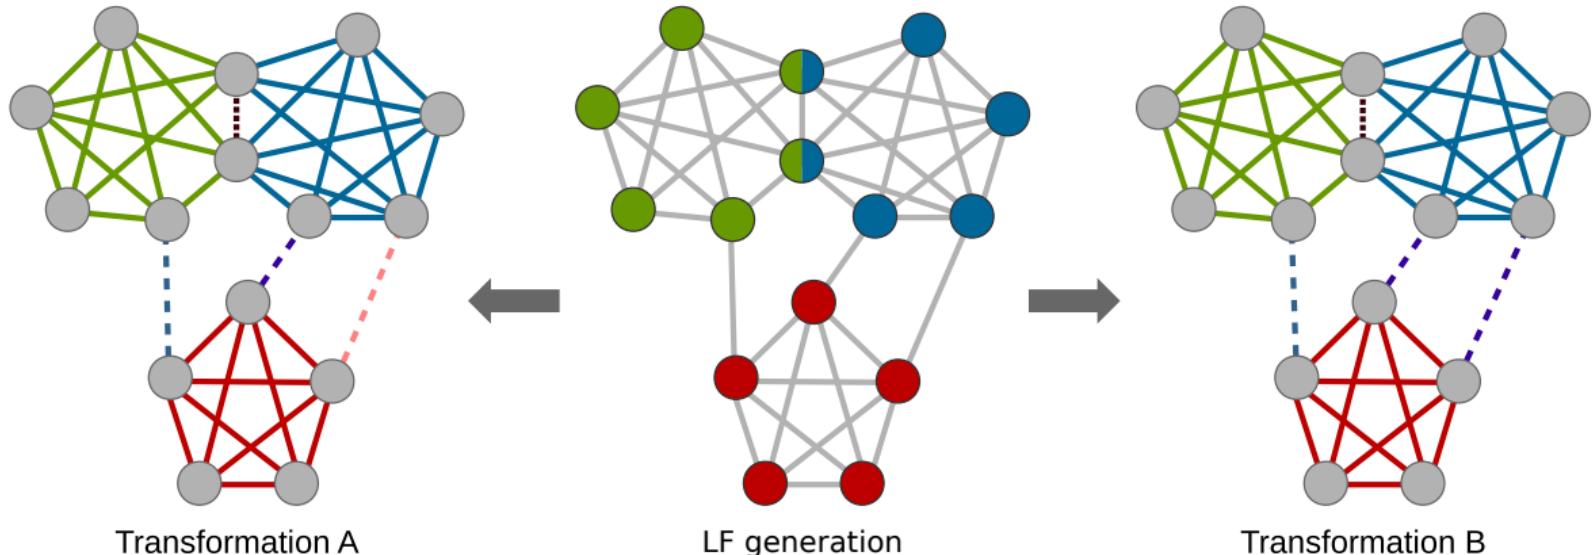

$$Q^*(L) = 2 \frac{|L| Q_{in}(L) + |L_{out}| Q_{ext}(L_{out})}{|L| + |L_{out}|}$$

Tests with LF benchmark

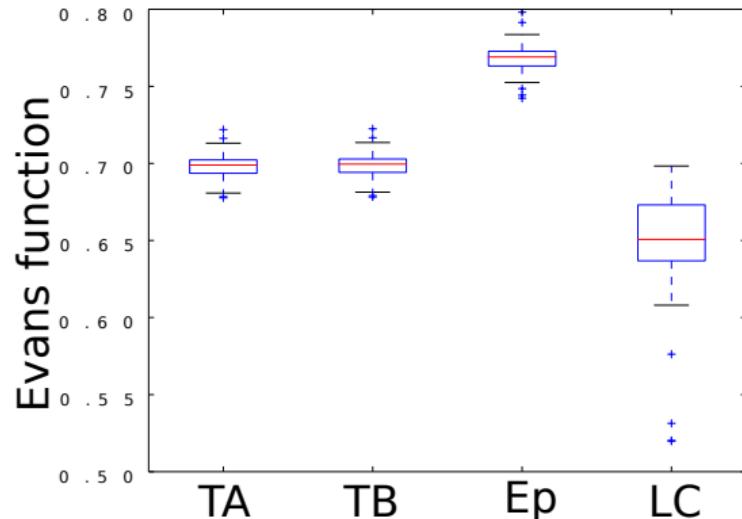

Test method

Ground truth generation

Results for Evans *et al.*

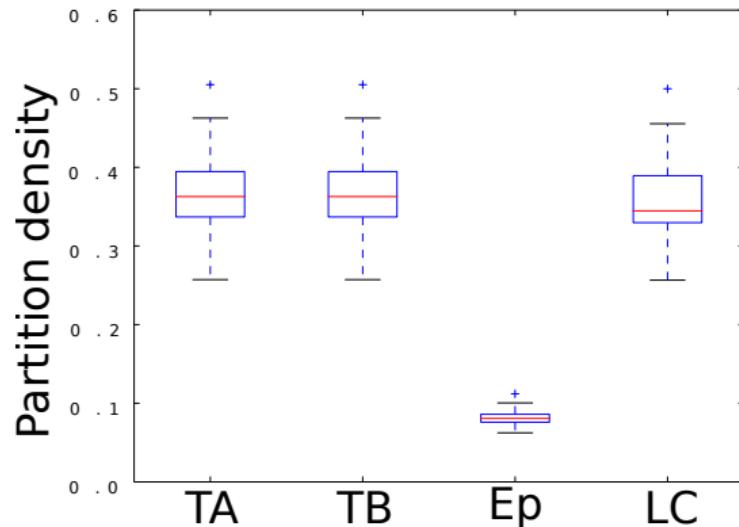

Highlight :

$$\begin{aligned} Q(TA) &< Q(E2) \\ Q(TA) &= Q(TB) \end{aligned}$$

FIGURE – Evaluation of **Ef** from Evans *et al.* on several partitions.

Results for the Partition density

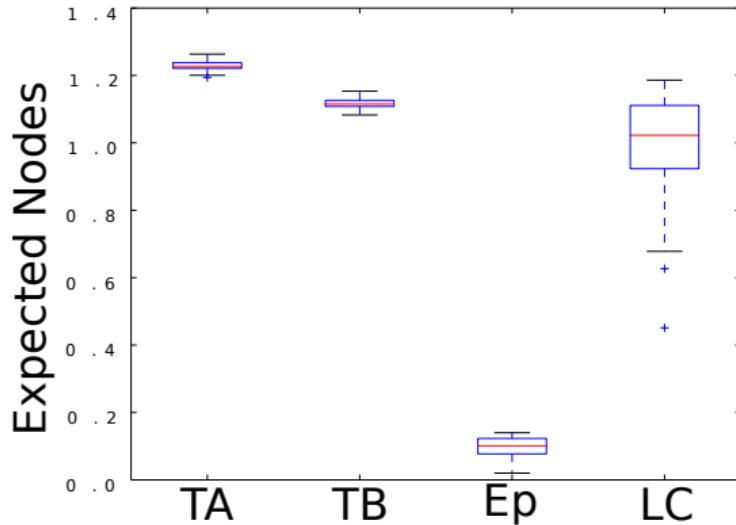

Highlight :

- $Q(TA) \leq Q(LC)$
- $Q(TA) = Q(TB)$

FIGURE – Evaluation of the **partition density** from Ahn *et al.* on several partitions.

Results for Expected Nodes

Highlight :

- $Q(TA) > Q(X)$
- $Q(TA) \neq Q(TB)$

FIGURE – Evaluation of **Expected Nodes** on several partitions.

Conclusion and perspectives

To sum up :

- Consider community of links instead of nodes.
- Definition of *Expected Nodes* to evaluate link partitions.
- On the tests, the ground truth is the best choice only for *Expected Nodes*.

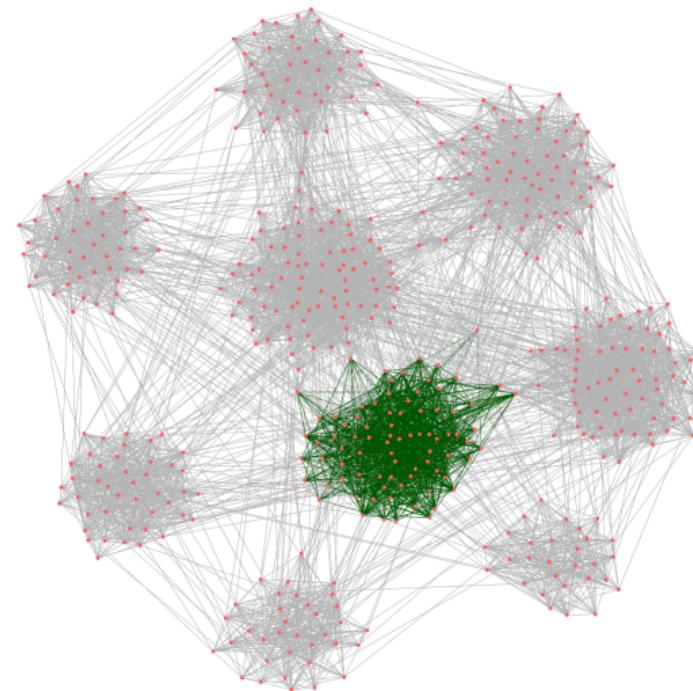

Perspectives

- Design an algorithm for maximizing *Expected Nodes*.
- More detailed comparisons between quality functions

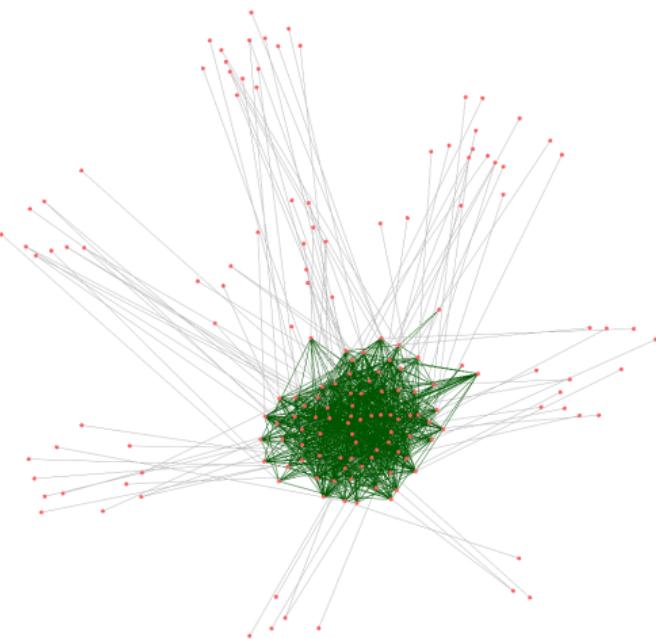

Questions ?

LF generation example

Green group :
a community in the
ground truth
